

# Sketching for Motzkin's Iterative Method for Linear Systems

Liza Rebrova

Department of Mathematics  
UCLA

Asilomar Conference on Signals, Systems, and Computers, November 2019

Joint work with Deanna Needell

## Model: overdetermined linear system

$$A \cdot x_* = b$$

$A$  is a tall  $m \times n$  matrix ( $m \gg n$ ) assumed to have full column rank. Notations:  $A_i$  - rows of  $A$ ,

$$\sigma_{min}^2 = eig_{min}(A^T A) = 1/\|A^{-1}\|_{L_2 \rightarrow L_2}^2$$

# Randomized Kaczmarz method

Starting at some  $x_0 \in \mathbb{R}^n$ :

1. Choose  $i = i(k) \in [m]$  with probability  $\|A_i\|_2^2 / \|A\|_F^2$
2. Define  $x_k := x_{k-1} + \frac{b_i - A_i^T x_{k-1}}{\|A_i\|^2} A_i$
3. Repeat until  $\|Ax_k - b\|_2 < \varepsilon$  (some threshold)

## Convergence theorem (Strohmer - Vershynin 2009)

*The randomized Kaczmarz converges to  $x_*$  linearly in expectation:*

$$\mathbb{E} \|x_k - x_*\|_2^2 \leq \left(1 - \frac{1}{\tilde{\kappa}(A)}\right)^k \|x_0 - x_*\|_2^2.$$

where  $\tilde{\kappa}(A) = \frac{\|A\|_F^2}{\sigma_{\min}^2(A)}$  is a condition number of  $A$ .

## Relaxation (Motzkin's) method

Starting at some  $x_0 \in \mathbb{R}^n$ :

1. Choose

$$i := \operatorname{argmax}_{j \in [m]} (A_j x_k - b_j)^2$$

2. Define  $x_k := x_{k-1} + \frac{b_i - A_i^T x_{k-1}}{\|A_i\|^2} A_i$

3. Repeat until  $\|Ax_k - b\|_2 < \varepsilon$

### Theorem (Haddock - Needell 2018)

*The randomized Kaczmarz converges to  $x_*$  linearly in expectation:*

$$\|x_k - x_*\|_2^2 \leq \prod_{i=0}^{k-1} \left( 1 - \frac{\sigma_{\min}^2(A)}{4\gamma_i(A)} \right) \|x_0 - x_*\|_2^2,$$

*where  $\gamma_i(A) = \|Ax_i - Ax_*\|_2^2 / \|Ax_i - Ax_*\|_\infty^2$  is a dynamic range of the  $i$ -th residual.*

## Randomized Kaczmarz method:

- could get stuck in “similar” equations
- iterations are fast
- provable (convergence in expectation)

## Motzkin method:

- iterations make good progress
- slower iterations (search of the best equation is slow...)
- dynamic range is theoretically estimated only in some special cases

E.g., for  $A$  with independent standard normal entries

$$\gamma_k \sim \|A\|_F^2 n / \log(m - k),$$

which shows accelerated convergence when  $\log(m - k) > n$ .

# Sketch-and-project framework

Gower - Richtárik (2015):

instead of  $Ax = b$ , solve  $S^T Ax = S^T b$

$S = m \times s$  sketch matrix, assume  $s \ll m$

idea: to solve an easier  $s \times n$  system instead of the original

Iteration:

- Pick random  $S$  from some distribution
- $x_k := x_{k-1} + (S^T A)^\dagger (S^T b - S^T Ax_k)$

Note! Taking  $S = e_k$  (randomly at each iteration) makes  $S^T A = A_k$  ( $k$ -th row) and recovers randomized Kaczmarz method.

# Sketching for Motzkin

Idea: instead of

$$i := \arg \max_{j \in [m]} (A_j x_k - b_j)^2$$

search over some smaller subset of indices.

## Sketching for Motzkin

For example, for some subset  $J \subset [m]$ ,

$$i := \arg \max_{j \in J} (A_j x_k - b_j)^2 = \arg \max_{j \in J} ((A_J)_j x_k - (b_J)_j)^2$$

**Block sketching** is sketching  $A$  with

$S =$  randomly placed identity completed by zeroes.

Also known as **SKM method**.

## (SKM) Sampling Kaczmarz Motzkin Method

Starting at some  $x_0 \in \mathbb{R}^n$ :

1. Choose  $\tau_k \subset [m]$  to be a sample of size  $\beta$  constraints chosen uniformly at random among the rows of  $A$ .
2. From the  $\beta$  rows, choose  $i := \arg \max_j (A_j x_k - b_j)^2$
3. Define  $x_k := x_{k-1} + \frac{b_i - A_i x_{k-1}}{\|A_i\|^2} A_i$
4. Repeat until convergence

DeLoera, Haddock, Needell (2019)

“A Sampling Kaczmarz-Motzkin Algorithm for Linear Feasibility”  
SIAM Journal on Scientific Computing, vol. 39, 5, 66–87, 2017.

## (GSM) Gaussian sketched Motzkin

Starting at some  $x_0 \in \mathbb{R}^n$ :

1. Sketch the system:  $A_S := S^T A$  and  $b_S := S^T b$ , where  $S$  is an  $m \times s$  standard normal matrix.
2. Choose  $i := \operatorname{argmax}_{j \in [s]} ((A_S)_j x_k - (b_S)_j)^2$
3. Define  $x_k := x_{k-1} + \frac{(b_S)_i - (A_S)_i x_{k-1}}{\|(A_S)_i\|^2} (A_S)_i$
4. Repeat until convergence

$$\begin{matrix} s \\ \boxed{S^T A} \\ n \end{matrix} = \begin{matrix} \boxed{s_{ij} \sim N(0, 1)} \\ m \end{matrix} \cdot \begin{matrix} \boxed{A} \end{matrix}$$

## (sGSM) Sparse Gaussian Sketched Motzkin

Starting at some  $x_0 \in \mathbb{R}^n$ :

1. Sketch the system:  $A_S := S^T A$  and  $b_S := S^T b$ , where  $S$  has an  $s \times s$ . gaussian block.
2. Choose  $i := \operatorname{argmax}_{j \in [s]} ((A_S)_j x_k - (b_S)_j)^2$
3. Define  $x_k := x_{k-1} + \frac{(b_S)_i - (A_S)_i x_{k-1}}{\|(A_S)_i\|^2} (A_S)_i$
4. Repeat until convergence

# Theoretical bounds

## Theorem (Rebrova Needell 2019)

*The GSM converges to  $x_*$  linearly in expectation:*

$$\mathbb{E}\|x_k - x_*\|_2^2 \leq \left(1 - c \frac{\log(s)}{\tilde{\kappa}(A)}\right)^k \|x_0 - x_*\|_2^2.$$

*The sGSM converges to  $x_*$  linearly in expectation:*

$$\mathbb{E}\|x_k - x_*\|_2^2 \leq \left(1 - c \frac{\log s}{\tilde{\kappa}(A')}\right)^k \|x_0 - x_*\|_2^2.$$

*Here,  $c > 0$  is an absolute constant,  $\tilde{\kappa}(A) = \frac{\|A\|_F^2}{\sigma_{\min}^2(A)}$  is the standard rate, and  $A'$  is the worst conditioned  $s \times n$  row submatrix of  $A$ , namely,*

$$\tilde{\kappa}(A') = \operatorname{argmin}_{A_\tau} \tilde{\kappa}(A_\tau).$$

## Well-conditioned sub-blocks

Every standardized matrix admits a good row paving:

### Theorem

*Let  $A$  be a  $m \times n$  matrix. For any  $\delta \in (0, 1)$ , there exists a partition on at most  $\|A\|^2 \log m \delta^{-2}$  blocks, such that for every block  $A_\tau$*

$$1 - \delta \leq \sigma_{\min}(A_\tau) \leq \sigma_{\max}(A_\tau) \leq 1 + \delta.$$

Moreover,

- Good paving could be constructed in poly-time
- For incoherent matrices a random row partition is likely a good paving

(Tropp, Popa, Bourgain, Tzafriri, Vershynin)

## Bits of proof

- An analogue of the dynamic range

$$\mathbb{E} \frac{\|b_S - A_S x_k\|_\infty^2}{\|(A_S)_i\|_2^2} \geq \frac{(\mathbb{E} \|b_S - A_S x_k\|_\infty)^2}{\mathbb{E}(\|(A_S)_i\|_2^2)}$$

by Jensen's inequality: the function  $(x, y) \mapsto x^2/y$  is convex on the positive orthant

- Numerator:

$$\mathbb{E}_S \|S^T A(x_* - x_k)\|_\infty = \mathbb{E} \max_{i \in [s]} \langle S_i, v \rangle \geq c \|v\|_2 \sqrt{\log s}$$

estimate for the max of independent  $N(0, 1)$  random variables

- Denominator:

$$\mathbb{E} \|(S^T A)_i\|_2^2 = \|A\|_F^2 \quad (\text{direct computation})$$

# Experiments on artificial datasets

$A = 5000 \times 100$  i.i.d. matrix:  
 $N(0, 1)$  model and  $Unif[0.8, 1]$  model

## Experiments on artificial datasets-2

$A = 5000 \times 100$  i.i.d. matrix:  
 $Unif[0.8, 1]$  model

# Experiments on real world datasets

Left: GAS dataset ( $1000 \times 128$ )  
Right: COVTYPE dataset ( $5000 \times 54$ )

# GSM method: dependence on sketch size

$A = 5000 \times 500$  i.i.d. matrix:

Left:  $N(0, 1)$  model

Right:  $Unif[0.8, 1]$  model

# SparseGSM method: dependence on sketch size

$A = 5000 \times 500$  i.i.d. matrix:

$Unif[0.8, 1]$  model

Time until  $1e-1$  error, averaged over 10 iterations

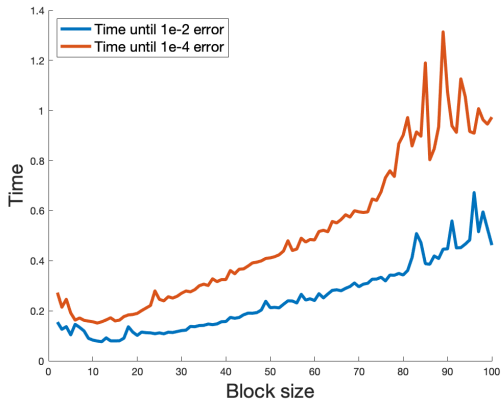

# SparseGSM method: dependence on sketch size

$A = 5000 \times 100$  i.i.d. matrix:

$Unif[0.8, 1]$  model

Time until  $1e-2/1e-4$  error, averaged over 20 iterations

# Conclusions

- We consider 3 ways to sketch Motzkin's iterative method: SKM, GSM and sparseGSM
- We provide theoretical guarantees for the accelerated convergence of GSM (and sparseGSM for a well-conditioned matrix)
- We demonstrate experimentally some cases when sketched methods work better than both Kaczmarz and Motzkin (and when gaussian sketches outperform SKM)
- We investigate experimentally optimal block size for the sparseGSM method

Thanks for your attention!
